Africast-Time Series Analysis & Forecasting Using R

8. ARIMA models

Outline

- 1 ARIMA models
- 2 Seasonal ARIMA models
- 3 Forecast ensembles

Outline

- 1 ARIMA models
- 2 Seasonal ARIMA models
- 3 Forecast ensembles

AR: autoregressive (lagged observations as inputs)

I: integrated (differencing to make series stationary)

MA: moving average (lagged errors as inputs)

AR: autoregressive (lagged observations as inputs)

I: integrated (differencing to make series stationary)

MA: moving average (lagged errors as inputs)

An ARIMA model is rarely interpretable in terms of visible data structures like trend and seasonality. But it can capture a huge range of time series patterns.

Stationarity

Definition

If $\{y_t\}$ is a stationary time series, then for all s, the distribution of (y_t,\ldots,y_{t+s}) does not depend on t.

Stationarity

Definition

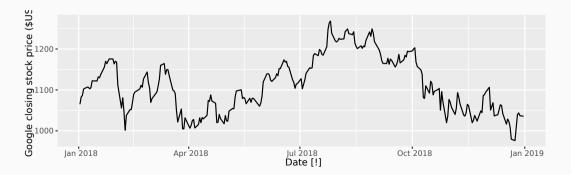

If $\{y_t\}$ is a stationary time series, then for all s, the distribution of (y_t,\ldots,y_{t+s}) does not depend on t.

A **stationary series** is:

- roughly horizontal
- constant variance
- no patterns predictable in the long-term

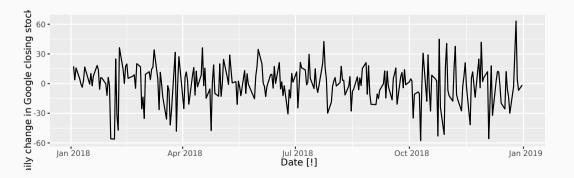

Stationary?

```
gafa_stock |>
  filter(Symbol == "G00G", year(Date) == 2018) |>
  autoplot(Close) +
  labs(y = "Google closing stock price ($US)")
```

Stationary?

```
gafa_stock |>
filter(Symbol == "GOOG", year(Date) == 2018) |>
autoplot(difference(Close)) +
labs(y = "Daily change in Google closing stock price")
```

Differencing

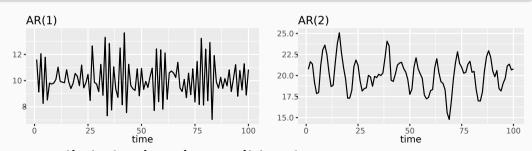

- Differencing helps to stabilize the mean.
- The differenced series is the *change* between each observation in the original series.
- Occasionally the differenced data will not appear stationary and it may be necessary to difference the data a second time.
- In practice, it is almost never necessary to go beyond second-order differences.

Autoregressive models

Autoregressive (AR) models:

$$y_{t} = c + \phi_{1}y_{t-1} + \phi_{2}y_{t-2} + \dots + \phi_{p}y_{t-p} + \varepsilon_{t},$$

where ε_t is white noise. A multiple regression with **lagged** values of y_t as predictors.

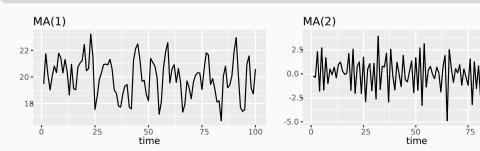

Cyclic behaviour is possible when $p \geq 2$.

Moving Average (MA) models

Moving Average (MA) models:

$$y_t = c + \varepsilon_t + \theta_1 \varepsilon_{t-1} + \theta_2 \varepsilon_{t-2} + \dots + \theta_q \varepsilon_{t-q},$$

where ε_t is white noise. A multiple regression with **lagged errors** as predictors. Don't confuse with moving average smoothing!

100

Autoregressive Moving Average models:

$$\begin{aligned} y_t &= c + \phi_1 y_{t-1} + \dots + \phi_p y_{t-p} \\ &+ \theta_1 \varepsilon_{t-1} + \dots + \theta_q \varepsilon_{t-q} + \varepsilon_t. \end{aligned}$$

Autoregressive Moving Average models:

$$\begin{aligned} y_t &= c + \phi_1 y_{t-1} + \dots + \phi_p y_{t-p} \\ &+ \theta_1 \varepsilon_{t-1} + \dots + \theta_q \varepsilon_{t-q} + \varepsilon_t. \end{aligned}$$

lacksquare Predictors include both **lagged values of** y_t **and lagged errors.**

Autoregressive Moving Average models:

$$\begin{aligned} y_t &= c + \phi_1 y_{t-1} + \dots + \phi_p y_{t-p} \\ &+ \theta_1 \varepsilon_{t-1} + \dots + \theta_q \varepsilon_{t-q} + \varepsilon_t. \end{aligned}$$

lacktriangleright Predictors include both lagged values of y_t and lagged errors.

Autoregressive Integrated Moving Average models

- Combine ARMA model with differencing.
- d-differenced series follows an ARMA model.
- Need to choose p, d, q and whether or not to include c.

ARIMA(p, d, q) model

- AR: p =order of the autoregressive part
 - I: d =degree of first differencing involved
- MA: q =order of the moving average part.
 - White noise model: ARIMA(0,0,0)
 - Random walk: ARIMA(0,1,0) with no constant
 - Random walk with drift: ARIMA(0,1,0) with const.
 - **AR**(p): ARIMA(p,0,0)
 - MA(q): ARIMA(0,0,q)

```

Understanding ARIMA models

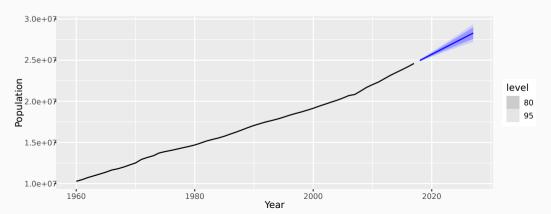

- If c=0 and d=0, the long-term forecasts will go to zero.
- If c=0 and d=1, the long-term forecasts will go to a non-zero constant.
- If c=0 and d=2, the long-term forecasts will follow a straight line.
- If $c \neq 0$ and d = 0, the long-term forecasts will go to the mean of the data.
- If $c \neq 0$ and d = 1, the long-term forecasts will follow a straight line.
- If $c \neq 0$ and d = 2, the long-term forecasts will follow a quadratic trend.

Understanding ARIMA models

Forecast variance and d

- The higher the value of *d*, the more rapidly the prediction intervals increase in size.
- For d=0, the long-term forecast standard deviation will go to the standard deviation of the historical data.

```
fit |>
  forecast(h = 10) |>
  filter(Country == "Australia") |>
  autoplot(global_economy)
```

Hyndman and Khandakar (JSS, 2008) algorithm:

- Select no. differences d via KPSS test.
- \blacksquare Select p, q and inclusion of c by minimising AICc.
- Use stepwise search to traverse model space.

Hyndman and Khandakar (JSS, 2008) algorithm:

- Select no. differences d via KPSS test.
- \blacksquare Select p, q and inclusion of c by minimising AICc.
- Use stepwise search to traverse model space.

$$\begin{aligned} &\mathsf{AICc} = -2\log(L) + 2(p+q+k+1) \left[1 + \frac{(p+q+k+2)}{T-p-q-k-2} \right] \\ &\mathsf{where}\ L \ \mathsf{is}\ \mathsf{the}\ \mathsf{maximised}\ \mathsf{likelihood}\ \mathsf{fitted}\ \mathsf{to}\ \mathsf{the}\ \mathit{differenced} \\ &\mathsf{data,}\ k=1\ \mathsf{if}\ c \neq 0\ \mathsf{and}\ k=0\ \mathsf{otherwise}. \end{aligned}$$

Hyndman and Khandakar (JSS, 2008) algorithm:

- Select no. differences d via KPSS test.
- \blacksquare Select p, q and inclusion of c by minimising AICc.
- Use stepwise search to traverse model space.

$$\begin{aligned} &\mathsf{AICc} = -2\log(L) + 2(p+q+k+1) \left[1 + \frac{(p+q+k+2)}{T-p-q-k-2} \right] \\ &\mathsf{where}\ L \ \mathsf{is}\ \mathsf{the}\ \mathsf{maximised}\ \mathsf{likelihood}\ \mathsf{fitted}\ \mathsf{to}\ \mathsf{the}\ \mathit{differenced} \\ &\mathsf{data,}\ k=1\ \mathsf{if}\ c \neq 0\ \mathsf{and}\ k=0\ \mathsf{otherwise}. \end{aligned}$$

Note: Can't compare AICc for different values of d.

Step1: Select current model (with smallest AICc) from:

 $\mathsf{ARIMA}(2,d,2)$

 $\mathsf{ARIMA}(0,d,0)$

 $\mathsf{ARIMA}(1,d,0)$

 $\mathsf{ARIMA}(0,d,1)$

```
Step1: Select current model (with smallest AICc) from:
```

 $\mathsf{ARIMA}(2,d,2)$

ARIMA(0, d, 0)

ARIMA(1, d, 0)

ARIMA(0,d,1)

Step 2: Consider variations of current model:

- vary one of p, q, from current model by ± 1 ;
- lacksquare p,q both vary from current model by ± 1 ;
- Include/exclude c from current model.

Model with lowest AICc becomes current model.

```
Step1: Select current model (with smallest AICc) from:
```

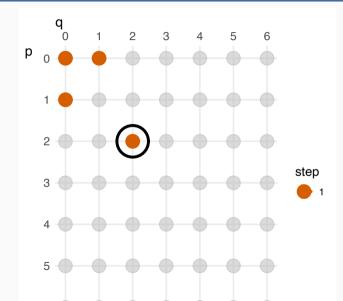

- ARIMA(2, d, 2)
- ARIMA(0, d, 0)
- ARIMA(1, d, 0)
- ARIMA(0, d, 1)

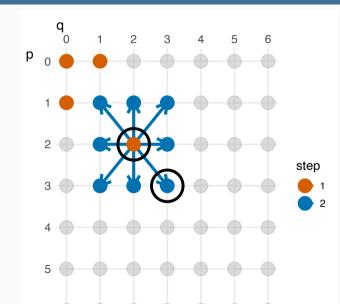

Step 2: Consider variations of current model:

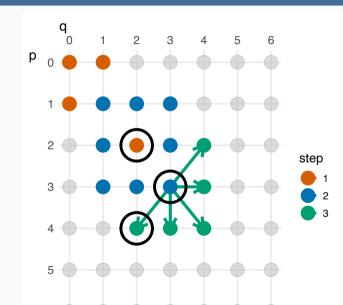

- vary one of p, q, from current model by ± 1 ;
- ightharpoonup p,q both vary from current model by ± 1 ;
- Include/exclude c from current model.

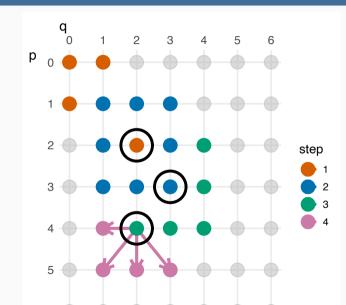

Model with lowest AICc becomes current model.

Repeat Step 2 until no lower AICc can be found.

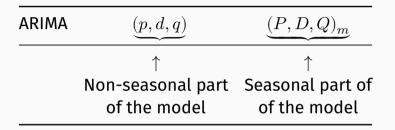

Outline

- 1 ARIMA models
- 2 Seasonal ARIMA models
- 3 Forecast ensembles

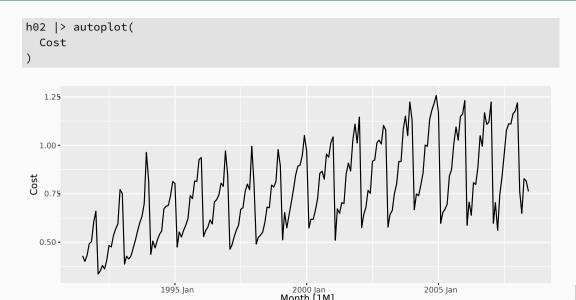

Seasonal ARIMA models

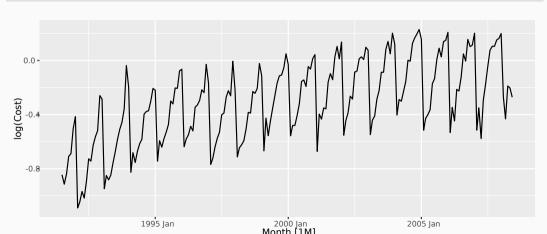

- lacktriangleq m = number of observations per year.
- $lue{d}$ first differences, D seasonal differences
- lacksquare p AR lags, q MA lags
- lacksquare P seasonal AR lags, Q seasonal MA lags

Seasonal and non-seasonal terms combine multiplicatively

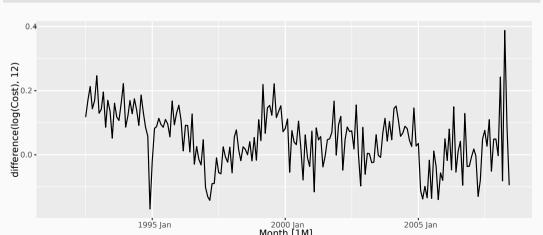

```
h02 <- PBS |>
filter(ATC2 == "H02") |>
summarise(Cost = sum(Cost) / 1e6)
```

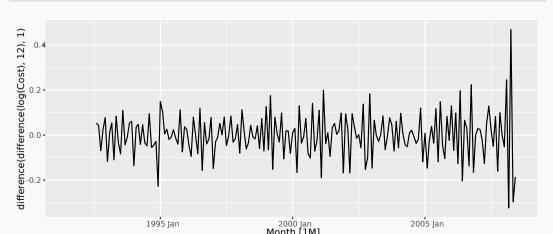

```
h02 |> autoplot(
  log(Cost)
)
```

```
h02 |> autoplot(
  log(Cost) |> difference(12)
)
```

```
h02 |> autoplot(
  log(Cost) |> difference(12) |> difference(1)
)
```

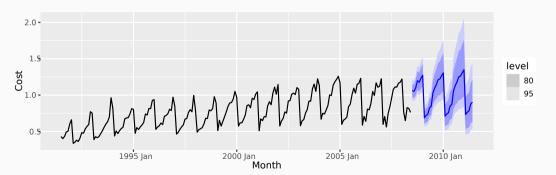

Example: US electricity production

```
h02 |>
 model(arima = ARIMA(log(Cost))) |>
 report()
Series: Cost
Model: ARIMA(2,1,0)(0,1,1)[12]
Transformation: log(Cost)

                                                            0.213
sigma^2 estimated as 0.004049: log likelihood=254
```

BTC=-456

3.

```
fit |>
  forecast() |>
  autoplot(h02) +
  labs(y = "H02 Expenditure ($AUD)", x = "Year")
```

Outline

- 1 ARIMA models
- 2 Seasonal ARIMA models

3 Forecast ensembles

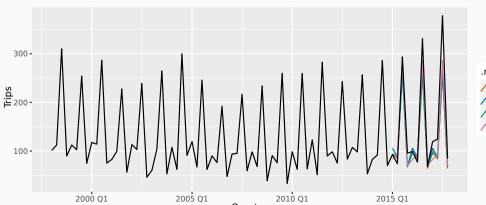

Forecast ensembles

```
train <- tourism |>
  filter(year(Quarter) <= 2014)
fit <- train |>
  model(
    ets = ETS(Trips),
    arima = ARIMA(Trips),
    snaive = SNAIVE(Trips)
) |>
  mutate(mixed = (ets + arima + snaive) / 3)
```

- Ensemble forecast mixed is a simple average of the three fitted models.
- forecast() will produce distributional forecasts taking into account the correlations between the forecast errors of the component models.

Forecast ensembles

```
fc <- fit |> forecast(h = "3 years")
fc |>
  filter(Region == "Snowy Mountains", Purpose == "Holiday") |>
  autoplot(tourism, level = NULL)
```

.model
// arima
// ets

mixed
snaive
